## Summary

Polyhedral gravity models are ubiquitous for modeling the gravitational field of irregular bodies, such as asteroids and comets. We present an open-source C++ library for the efficient, parallelized computation of a polyhedral gravity model. We also provide a Python interface to the library using *pybind11*. The library is particularly focused on delivering high performance and scalability which we achieve through vectorization and parallelization with *xsimd* and *thrust*, respectively. The library supports many common formats, such as *.stl*, *.off*, *.ply*, *.mesh* and *tetgen's .node* and *.face*.

## Statement of Need

The complex gravitational fields of irregular bodies, such as asteroids and comets, are often modeled using polyhedral gravity models as they provide an analytic solution for the computation of the gravitational potential, acceleration (and second derivative) given a mesh of the body (Tsoulis, 2012; Tsoulis & Gavriilidou, 2021). The computation of the gravitational potential and acceleration is a computationally expensive task, especially for large meshes, which can however benefit from parallelization either over computed targets points for which we seek potential and acceleration or over the mesh. Thus, a high-performance implementation of a polyhedral gravity model is desirable.

While some research code for these models exists, they are not focused on usability and limited to FORTRAN **TODO LINK** and proprietary software like MATLAB **TODO LINK**. There is a lack of well-documented, maintained open-source implementations, particularly in modern programming languages and with a focus on scalability and performance.

The presented software has already seen application in several research works. It has been used to optimize trajectories around the highly irregular comet 67P/Churyumov-Gerasimenko (Marák et al., 2023). Further, it has been used to study the effectiveness of so-called neural density fields (Izzo & Gómez, 2022), where it can serve as a ground truth and to pretrain neural networks (Schuhmacher et al., 2023). **TODO\_add\_more\_examples**

Thus, overall this model is highly versatile and can be used in a wide range of applications. We hope it will enable further research in the field, especially related to recent machine learning techniques, which typically rely on Python implementations.

## Polyhedral Model

On a mathematical level, the implemented model follows the approach by Petrović (Petrović, 1996) as refined by Tsoulis and Petrović (Tsoulis & Petrović, 2001). A comprehensive

39 description of the mathematical foundations of the model is given in the associated student  
40 report ([Schuhmacher, 2022](#)).

41 Implementation-wise it makes use of the inherent parallelization opportunity of the approach  
42 as it iterates over the mesh. This parallelization is achieved via *thrust* which allows utilizing  
43 *OpenMP* and *Intel TBB*. On a finer scale, individual costly operations were investigated and,  
44 e.g., the arctan operations were vectorized using *xsimd*. On an application side, the user may  
45 use the implemented caching mechanism to avoid recomputation of mesh properties, such as  
46 the face normals.

47 Extensive tests using GoogleTest are used via GitHub Actions to ensure the (continued)  
48 correctness of the implementation.

## 49 Installation & Contribution

50 The library is available on GitHub <sup>1</sup> and can be installed with *pip* or from *conda* <sup>2</sup>. Build  
51 instructions using *CMake* are provided in the repository. The library is licensed under a GPL  
52 license.

53 The project is open to contributions via pull requests with instructions on how to contribute  
54 provided in the repository.

## 55 Usage Instructions

56 We provide detailed usage instructions in the technical documentation on ReadTheDocs <sup>3</sup>.  
57 Additionally, a minimal working example is given in the repository readme and more extensive  
58 examples as a *Jupyter* notebook <sup>4</sup>.

## 59 Acknowledgements

60 The authors would like to thank Dario Izzo and Emmanuel Blazquez for their feedback on the  
61 original model implementation.
